#### **ABSTRACT**

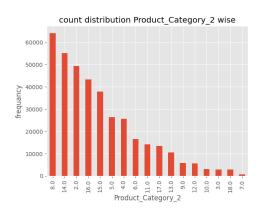

## This is report

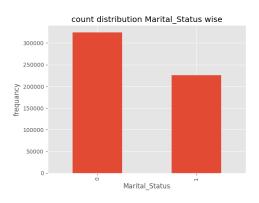

## 1 Experiment 1: EDA (Exploratory Data Analysis)

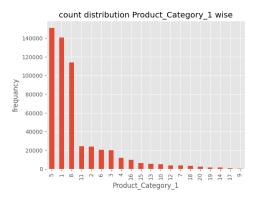

## 1.1 Plots

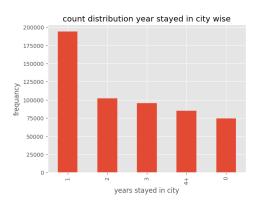

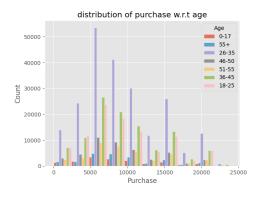

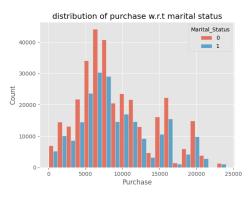

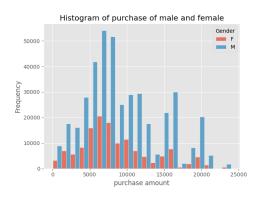

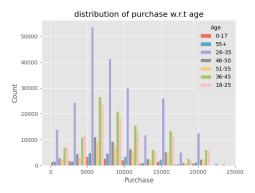

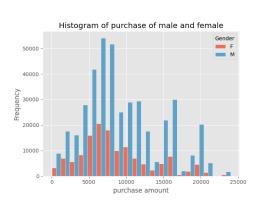

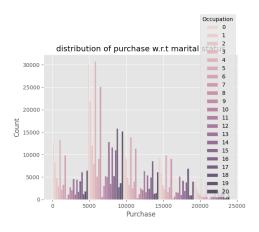

#### 1.2 Procedure to EDA

1. First, dropped the User\_ID and "Product\_ID" because IDs do not make any sense in the model.

## 2. Handling the NaN values

- In Product\_category\_3, we had 69.67% NaN values, so we dropped it.
- In Product\_category\_2, I used a **forward fill**. From the plot of **"count distribution product\_category\_2 wise"**, it is evident that using a mode fill would make our model more biased towards one category of product.

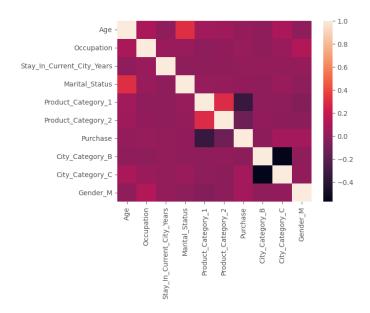

Figure 1: heat map for correlation for diffetent features

|    | Age | Occupation | Stay_In_Current_City_Years | Marital_Status | Product_Category_1 | Product_Category_2 | Purchase | City_Category_B | City_Category_C | Gender_M |
|----|-----|------------|----------------------------|----------------|--------------------|--------------------|----------|-----------------|-----------------|----------|

| 10 | 35  | 20         | 1                          | 1              | 5                  | 11.0               | 5254     | 0               | 0               | 1        |
| 11 | 35  | 20         | 1                          | 1              | 8                  | 11.0               | 3957     | 0               | 0               | 1        |
| 12 | 35  | 20         | 1                          | 1              | 8                  | 11.0               | 6073     | 0               | 0               | 1        |

Figure 2: Data after EDA

- 3. Used one-hot encoding for gender and city\_category.
- 4. Replaced the values for stay\_in\_city\_years using the following code: df['Stay\_In\_Current\_City\_Years'].replace('2':2, '4+':4, '3':3, '1':1, '0':0, inplace=True)
- 5. For Age, replaced using the following code:

  df ['Age'].replace('0-17':17, '55+':56, '26-35':35, '46-50':50,
  '51-55':55, '36-45':45, '18-25':25, inplace=True) because this
  features have **ordinal nature** so there wights matter in model
- 6. and Occupation, Product category 1 & 2 should remain as it is to avoid feature complexity

## 2 Experiment 2

- With out feature scaling: The value of Mean squared error (MSE) with out feature scaling came out 22081144.710634716
- With feature scaling: The value of Mean squared error (MSE) with out feature scaling came out 22081144.71063472
- we observe no difference in the value of MSE

## 3 Experiment 3

Table 1: MSE values for different learning rates for scaled data

| sr. no. | lr      | MSE                    |
|---------|---------|------------------------|
| 0       | 0.00001 | $2.884403\times10^{7}$ |
| 1       | 0.00010 | $2.517077 \times 10^7$ |
| 2       | 0.00100 | $2.209787 \times 10^7$ |
| 3       | 0.01000 | 2.208141e+07           |
| 4       | 0.10000 | $2.208752 \times 10^7$ |
| 5       | 0.50000 | $2.215061 \times 10^7$ |

Table 2: MSE values for different learning rates for unscaled data

| sr. no. | lr      | MSE          |  |  |
|---------|---------|--------------|--|--|
| 0       | 0.00001 | 2.707129e+07 |  |  |
| 1       | 0.00010 | 2.433942e+07 |  |  |
| 2       | 0.00100 | 2.213294e+07 |  |  |
| 3       | 0.01000 | NaN          |  |  |
| 4       | 0.10000 | NaN          |  |  |
| 5       | 0.50000 | NaN          |  |  |

#### 3.1 Observations

- For lr = 0.01 the MSE is minimum that means lr = 0.01 is optimal hyper-parameter
- On unscaled data it is observed that for higher value of learning rate algorithm is not converging

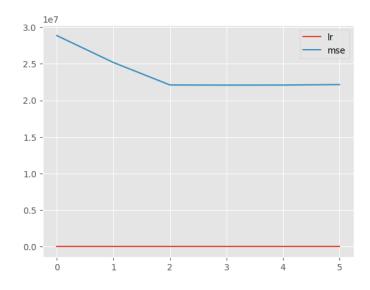

Figure 3: lr vs mse

## 4 Experiment 4

Applying ridge regression with learning rate = 0.01 on different value of alpha from 0 to 1 with increment of 0.1 we get below table

Table 3: MSE values for different alpha values

| Sr. No | Alpha | MSE                    |
|--------|-------|------------------------|
| 0      | 0.0   | $3.165392\times10^7$   |
| 1      | 0.1   | $3.274766 \times 10^7$ |
| 2      | 0.2   | $3.390877 \times 10^7$ |
| 3      | 0.3   | $3.512085 \times 10^7$ |
| 4      | 0.4   | $3.636997 \times 10^7$ |
| 5      | 0.5   | $3.764433 \times 10^7$ |
| 6      | 0.6   | $3.893397 \times 10^7$ |
| 7      | 0.7   | $4.023053 \times 10^7$ |
| 8      | 0.8   | $4.152699 \times 10^7$ |
| 9      | 0.9   | $4.281752 \times 10^7$ |
| 10     | 1.0   | $4.409729 \times 10^7$ |

From plot we can observe the increase in MSE as we increase the value of alpha for ridge regression This happens due to

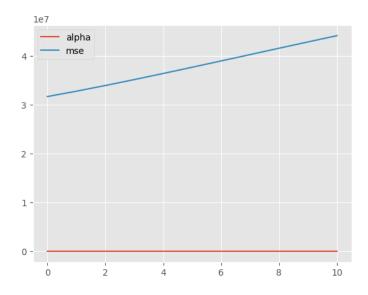

Figure 4: alpha vs mse

# 5 Experiment 5

Optimal hyper-parameter

$$lr = 0.01$$

$$\alpha = 0$$

Table 4: MSE values for different models

| Sr. No | model            | MSE                    |
|--------|------------------|------------------------|
| 1      | LIN_MODEL_CLOSED | $2.2081144\times10^7$  |
| 2      | LIN_MODEL_GRAD   | $2.208141\times10^{7}$ |
| 3      | LIN_MODEL_RIDGE  | $3.165392 \times 10^7$ |

- We observed a increase in MSE as we increase alpha this is due to less number of epochs where wights are updating slowly due to penalization.
- For closed model and gradient decent we observe no difference with respect to grad model
